IBEEM Data Meeting 2-7-25

- Discussed raw data formatting

  Data L0 folder will host all raw files

  one plot's data will get saved as a CSV in L1

- Test for mortality patterns in multiple ways:

  1) Look into <u>survival analysis</u>

  2) Calculate a plot average of mortality rate & compare changes at quadrat level

Unsure how this would handle 200 quadrats of data.

Adult densities will be continuous values & 200 lines on a plot is <u>unhelpful.</u>

Could be more intuitive/informative w/ type of data we have

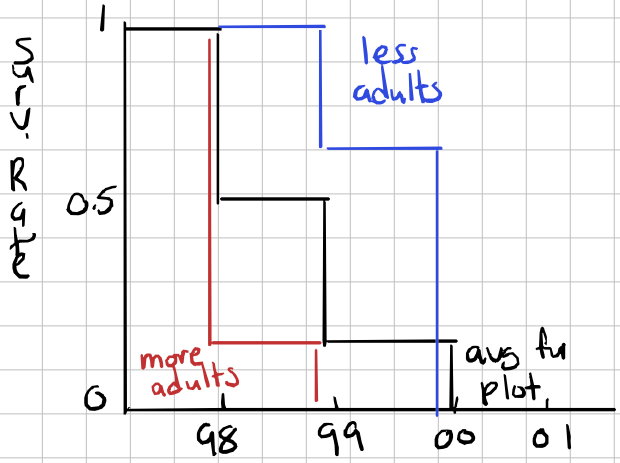

- Try on one species in one plot first!
- Group by cohorts to account for starting densities → use initial count as a covariate?

  ~~masting~~

<u>Graphs →</u>

1) Survival Analysis

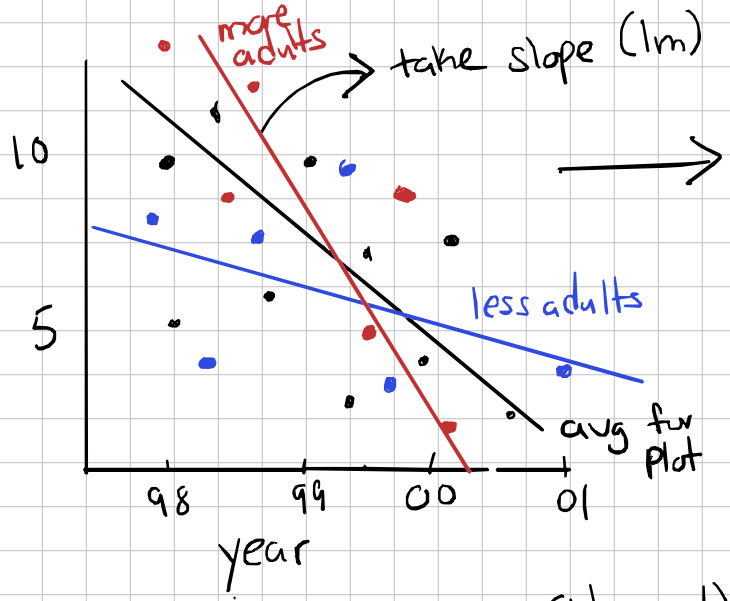

Cox Regression

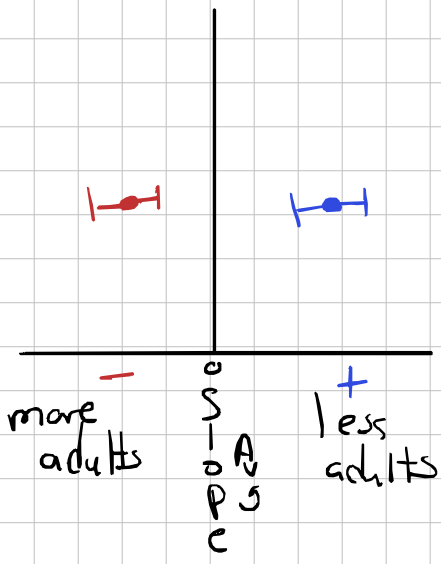

Find R package

Can this handle a ton of continuous data well?

2) Alternative - Potentially more informative?

1) count ~ year + (1|quad) → take slope for plot
2) count ~ year → for each quadrat, take slope
3) (quad slope - slope plot) ~ density measures
